

Phase 1 — Side Car Twin & Historical Archive

1 · SYSTEMS OF RECORD

2 · BACKUP REPLICATION

3 · LANDING AND EXTRACTION

4 · MODEL AND DECISION SUPPORT

5 · THE SURFACE

GATES — REAL DATA DOES NOT MOVE UNTIL

- Tim's agreement executed
Until then the same pipeline runs on synthetic and mock data, unchanged in shape.
- Luke has 20 Group access
Peer and Hawkins benchmark fields stay blank rather than guessed.
- TELUS service identity
Call history ingests through a Peterbilt-owned service account, never personal credentials.
- Signed agreements per system
Craig Allen's 16-system register is the substrate; agreements and access URLs are the first intake.
- Public / protected split held
Client-facing material stays separate from the protected origin thesis.
- Ledger-side objects verified
Undocumented CDK ledger objects are the first admin-access target.

Phase 1 scope — this week

Replicate the backup, land it, extract the 20 Group performance set, put one surface on top.

- Phase 1 — read-only flow
- Phase 2 — gated write-back

Reading the diagram

What each layer commits to, and what it deliberately does not.

Why the backup, and not the system

The entry point is a replicated CDK backup set, not the live dealer management system. That removes the largest objection in the room: there is no production risk, no integration window to negotiate, and no request for anyone at the dealership to change how they work. The restore is repeatable and disposable, so the whole build can be re-run from scratch.

Landing and extraction

A Postgres mirror carries the ASCII-safe schema already modelled at field level: 21 objects, 443 confidence-tagged fields, generated Postgres/Snowflake DDL and a preflight validator that must pass before load. Loads are idempotent and every row is stamped with its source backup ID. Undocumented ledger-side objects remain the first admin-access verification target. Three months are extracted with financial reporting keyed to the middle month, so the boundary months cannot distort it.

The model layer

An Azure-hosted open-source model with pinned weights and a versioned prompt set. The point of owning the weights is that the same input produces the same output next quarter: no silent vendor drift, and cost and latency that can be tuned rather than billed by the token. Numbers come from SQL. The model ranks and explains, it does not invent metric values, and every ranked item carries a reason that can be traced back to a row.

The surface, and what stays out

The deliverable is one 20 Group performance surface with the structured data underneath it and prioritised work lists beside it, ordered by urgency and strategy. In Phase 1 it is reference material the dealership can ignore without penalty. The dashed return path into CDK is Phase 2 and stays gated: nothing writes back into a live dealer management system before the agreement is executed and the access question is settled.

Provenance

Transcribed from the operator's hand sketches of 29 July 2026, the second of which adds the 20 Group performance single surface and the investment perspective, and reconciled against the held Peterbilt Atlantic Digital Twin record: the Luke reset defining a narrow read-only sidecar, the variance-worksheet intake covering spare parts and PACCAR ePortal integration, the CDK extraction sequence and field-level dictionary, the TELUS service-identity decision, and the agreement and access gates.

Repositories and surfaces

- [hawkins-twin-platform](#)
- [eve-hawkins-truck-mart](#)
- [Public architecture surface](#)

A replica-first build that proves value on a copy of the data before any production system, budget, or rollout decision is asked for.

01

Zero production risk

The build works from the CDK backup, never the live dealer management system. There is nothing to negotiate about touching a running dealership because nothing live is touched. The replica is read and the performance report is extracted from it, while the working system carries on unaffected. Synthetic data stands in until Tim Hawkins's agreement is executed and Luke Weatherbie has 20-Group access.

02

The model, owned outright

The analysis layer runs on an Azure-hosted open-source model with a pinned version, chosen deliberately over a vendor API. Pinning removes silent model drift, so results stay comparable month to month rather than shifting under an opaque update. Cost is controlled and predictable, set by hosting rather than by per-token vendor exposure, which matters once ingestion and reporting run on a recurring basis.

03

The surface is the asset

The visible output is a single 20 Group performance dashboard, but the asset underneath it is the structured data built to support that view. Craig Allen's 16-system register is the substrate the schema is modelled against, so the surface reflects how the dealer group's systems actually fit together. Client-facing material is kept separate from the protected internal origin thesis behind the build.

04

Staged commitment

Phase 1 buys evidence cheaply: a working replica, an extracted performance report, and a dashboard, built on synthetic and mock data with no dependency on the live CDK system. Whether to write back into CDK, connect the TELUS call-history service account, or roll the pattern out more widely are separate decisions, made later, once Phase 1 has been seen and judged on its own evidence rather than promised in advance.

05

Room to replicate the pattern

If Phase 1 holds up, the same replica-first pattern can be extended in both directions: the trucks and the field on one end, and PACCAR logistics and production systems on the other. Nothing here commits to that extension now. It is a later, optional decision that the current architecture is deliberately shaped to make straightforward, without requiring the underlying approach to be rebuilt or renegotiated.

The ask this week

This week, Phase 1 asks only for sign-off to build the replica and report on synthetic data.

Phase 1 is a replica, a landing, an extract and a surface. Write-back into CDK and any wider rollout across the trucks, the field and the PACCAR logistics and production systems are separate decisions, taken later, on evidence.
