Revenue Leakage for Discovery

The business case for a proven AI capability

Period	Discovery front-office briefing
Author	Tobias Polly, polly consulting e.U.

1 The opportunity

Revenue leaks quietly. Every time a booked record is edited after it is committed – a price reduced, a quantity trimmed, a discount reopened – value can slip away. Each change is small and buried in a system log, so no one sees the pattern. Across thousands of records it adds up, and today it stays invisible until the money is already gone.

We have built a capability that surfaces exactly where this is happening – which records, which people, which fields – and explains it in plain language inside Microsoft Teams, so a non-technical person can act on it the same day. You ask a question in your own words; you get a clear answer back. No spreadsheet archaeology, no report queue, no new tool to learn.

2 What we have proven

This is not a proposal on paper. The capability is live today on a finance workstream and has been tested on real data at scale. It finds the leakage, ranks it from worst to least, and narrates the pattern in a few plain sentences. And because every answer can be replayed and checked step by step, there is no black box to take on faith.

What we have proven	What it means for Discovery
It runs live on real data at scale	Not a pilot to build from scratch – a working capability to point at your data.
It finds and ranks the leakage	Quiet erosion becomes a short, prioritised list a person can act on.
Every answer is replayable	Your risk and audit teams can verify it themselves – nothing is taken on trust.
One engine serves many uses	The same tool works for matters, billing, staffing, and finance – not a one-off build.

Table 1: The capability is a set of results, not promises.

3 Why this is low-risk for Discovery

The engine already exists. Pointing it at a Discovery system is a configuration change, not a new platform to design, buy, and de-risk. You inherit the hardened version – the early mistakes were already made and paid for on prior work, so you start from the version that already survived a security review and real users.

Roughly three-quarters of any new rollout is reuse. Only the connection to your data and the questions you want answered are specific to you.

Capability	Status	For Discovery
The reasoning engine	Built	Reused unchanged
Answers in Microsoft Teams	Built	The same experience
Full audit trail	Built	Every answer replayable
Security posture	Built	Same scoped, revocable access
Connection to your data	To set up	Point it at the chosen system
Analysis workspace	To set up	Stood up per question, nothing kept

Table 2: What you are funding is the retargeting, not another platform.

4 Built to pass your security review

The security question is deliberately kept small. We query your live systems and keep no standing copy of your data: the analysis is built for the question you asked and discarded when it is answered, so there is no second database of sensitive records to secure. Access to your systems is registered inside your own environment, and you keep the power to revoke it at any time. Every answer is logged and can be replayed. Nothing leaves your cloud, and the AI models run inside your own tenant – swappable for newer ones as they arrive.

For a team that has been let down by vendors before, the point is simple: nothing here asks you to trust a black box. Access is scoped, revocable, and observable from end to end.

5 What it takes, and the decision

Standing this up is a short, low-risk sequence rather than a project: connect the engine to the chosen Discovery system, validate its answers against a period you already know, and open it to users in Teams. Because there is nothing new to build, the path from decision to a working answer is measured in weeks, not quarters.

The decision in front of you is which system to point it at first – the one where quiet edits are most likely turning into lost revenue.

The bottom line. The platform is already built and running. Discovery does not fund another system; it funds pointing a proven one at your data. That is the fastest, lowest-risk way to turn invisible leakage into a number you can act on.
